# DIFFERENTIAL COHOMOLOGY SEMINAR 4 (DRAFT)

#### TALK BY ALESSANDRO NANTO

In the last talk we learned the definition of a differential cohomology theory, as a sheaf valued in spectra on the site of manifolds. This talk continues our journey through differential cohomology theories, and focuses on the following three topics:

- (1) We want to learn how to construct non-trivial examples out of sheaves valued in chain complexes.
- (2) We want to understand how we can extend classical cohomology operations to the setting of differential cohomology theories.
- (3) We want to introduce suitable analogues of fiber-wise integration.

### 1. Abelian Groups, Spectra and the Heart

Let us start by reviewing the relation between abelian groups, rings and spectra.

**Definition 1.1.** Let  $n \in \mathbb{Z}$  and X be a spectrum, define  $\pi_n(X) := \pi_0(\Omega^{\infty + n}X) = \pi_0(X_{-n})$ . We call  $\pi_n$  the n-th homotopy group of X.

Remark 1.2. Note that since  $X_n \simeq \Omega^2 X_{n+2}$ , for any n, the set  $\pi_0(X_n)$  underlies the structure of an abelian group.

The category Sp underlies the structure of a symmetric monoidal  $\infty$ -category ([Lur17, Corollary 4.8.2.19]). Following [Lur17], we denote by  $\otimes$  the tensor product on Sp.

**Definition 1.3.** A commutative algebra object in Sp is called an  $\mathbb{E}_{\infty}$ -ring spectrum, see [Lur17, Definition 7.1.0.1]. Given an  $\mathbb{E}_{\infty}$ -ring spectrum R, denote by  $\operatorname{Mod}_R$  the corresponding category of left R-module spectra, see [Lur17, Definition 7.1.1.2].

Remark 1.4. The sphere spectrum  $\mathbb{S}$  acts as the monoidal unit of  $\mathbb{S}p$ , therefore it is a  $\mathbb{E}_{\infty}$ -ring spectrum. The category  $\mathrm{Mod}_{\mathbb{S}}$  is canonically equivalent to  $\mathbb{S}p$ .

**Definition 1.5.** Denote by  $\operatorname{Sp}_{\geq 0} \subseteq \operatorname{Sp}$  the full sub-category generated by *connective spectra*, i.e. spectra X such that  $\pi_n(X) \simeq 0$ , for all n < 0. Denote by  $\operatorname{Sp}^{\heartsuit} \subseteq \operatorname{Sp}_{\geq 0}$  the *heart of spectra*, i.e. the full sub-category generated by spectra X such that  $\pi_n(X) \simeq 0$ , for all n > 0.

We have the following result relating connective spectra and the heart, which follow immediately.

**Lemma 1.6.** Let X be a connective spectrum. The following are equivalent:

- (1) X is in the heart.
- (2)  $\pi_n(\Omega^{\infty}X) = 0$ , for all n > 0.
- (3)  $\operatorname{Hom}_{S_{\alpha}}(S, \Omega^{\infty}X) \simeq 0$ , for all connected, pointed spaces S.
- (4) X is local with respect to the class of maps  $\Sigma^{\infty}S \to 0$ , for every connected pointed space S.

The category  $\mathrm{Sp}_{\geq 0}$  is presentable and  $\pi_0$  induces an equivalence between the heart and  $\mathrm{Ab}$  ([Lur17, Proposition 1.4.3.6]). The heart is a sub-category of local objects of connective spectra, therefore the inclusion  $\mathrm{Ab} \simeq \mathrm{Sp}^{\heartsuit} \subseteq \mathrm{Sp}_{\geq 0}$  is a right adjoint. The category  $\mathrm{Sp}_{\geq 0}$  is closed under  $\otimes$  and, given X, Y connective spectra,

(1.7) 
$$\pi_0(X \otimes Y) \simeq \pi_0(X) \otimes \pi_0(Y)$$

see [Dav24, Theorem 2.3.28]

**Definition 1.8.** Given an abelian group A, denote by HA the (unique up to equivalence) spectrum of the heart such that  $\pi_0(HA) \simeq A$ . We call HA the Eilenberg-Mac Lane spectrum of A.

Date: 03.06.2025 & 17.06.2025

Using Equation (1.7), one can prove H, viewed as a functor  $Ab \to Sp$ , is lax monoidal. In particular, if R is a commutative ring, then HR is a connective  $\mathbb{E}_{\infty}$ -ring spectrum. On the other hand, if R is a connective  $\mathbb{E}_{\infty}$ -ring spectrum and M a connective module, then  $\pi_0(M)$  is a  $\pi_0(R)$ -module.

**Definition 1.9.** Given a commutative ring R, denote by  $\operatorname{Ch}(R) = \operatorname{Ch}(\operatorname{Mod}_R)$  the ordinary category of unbounded chain complexes. Let  $\mathcal{D}(R)$  be the  $\infty$ -localization of  $\operatorname{Ch}(R)$  at the class of quasi-isomorphisms.

Similar to the heart of spectra, given an  $\mathbb{E}_{\infty}$ -ring spectrum R, denote by  $\operatorname{Mod}_R^{\heartsuit} \subseteq \operatorname{Mod}_R$  the full subcategory generated by R-modules such that the underlying spectrum belongs to the heart of spectra.

**Theorem 1.10** (Stable Dold-Kan Correspondence). Let R be a commutative ring.

- (1)  $\operatorname{Mod}_R \simeq \operatorname{Mod}_{HR}^{\heartsuit}$  via taking Eilenberg-Mac Lane spectra.
- (2) The equivalence in (1) extends to an equivalence  $H: \mathcal{D}(R) \simeq \mathrm{Mod}_{HR}$  of symmetric monoidal  $\infty$ -categories.

*Proof.* (1) is [Lur17, Proposition 7.1.1.13], while (2) is [Lur17, Theorem 7.1.2.13]. 
$$\Box$$

An interesting consequence of Theorem 1.10 is the following:

Corollary 1.11. Given  $F \in \mathfrak{D}(R)$ , then  $\pi_n(HF) \simeq H_n(F)$ , for all  $n \in \mathbb{Z}$ .

Proof.

$$\pi_n(HF) = \pi_0(\Omega^{\infty+n}HF)$$

$$\stackrel{\textcircled{1}}{\simeq} \pi_0(\operatorname{Hom}_{\operatorname{\mathbb{S}p}}(\Sigma^n\mathbb{S}, HF))$$

$$\stackrel{\textcircled{2}}{\simeq} \pi_0(\operatorname{Hom}_{\operatorname{Mod}_{HR}}(\Sigma^nHR, HF))$$

$$\stackrel{\textcircled{3}}{\simeq} \pi_0(\operatorname{Hom}_{\mathfrak{D}(R)}(R[n], F))$$

$$\stackrel{\textcircled{4}}{\simeq} H_n(F)$$

① The functor  $\Omega^{\infty+n}$  is corepresented by the shifted sphere spectrum  $\Sigma^n \mathbb{S}$ . ② The forgetful functor  $\operatorname{Mod}_{HR} \to \operatorname{Mod}_{\mathbb{S}} \simeq \operatorname{Sp}$  is right adjoint to tensoring by HR and  $HR \otimes (\Sigma^n \mathbb{S}) \simeq \Sigma^n HR$ . ③ Theorem 1.10 ④  $\pi_0$  of the mapping space  $\operatorname{Hom}_{\mathcal{D}(R)}(R[n], F)$  is equivalent to the mapping space  $R[n] \to F$  in the ordinary derived category of R, i.e. homotopy classes of maps  $R[n] \to F$ , which correspond exactly to classes in  $H_n(F)$ .

## 2. More $\infty$ -categorical baggage

Let  $\mathcal{C}$  be a presentable  $\infty$ -category. The  $\infty$ -categorical background given in previous talks allows to conclude the existence of a number of functors. Here we give (somewhat) explicit formulas for one.

Remark 2.1. Recall &uc, the full sub-category of Mfd generated by Euclidean manfiolds  $\mathbb{R}^n$ , for every  $n \geq 0$ . Denote by j the inclusion functor &uc  $\subseteq$  Mfd. Recall that the restriction along j induces an equivalence  $\operatorname{Shv}(\operatorname{Mfd}, \mathcal{C}) \simeq \operatorname{Shv}(\operatorname{Euc}, \mathcal{C})$ , see [ADH21, Corollary A.5.6].

Evaluation at  $\{0\}$  induces an adjunction (Lconst,  $\Gamma$ ):  $\mathcal{C} \to \operatorname{Shv}(\mathcal{M}\mathrm{fd}, \mathcal{C})$ , where the functor  $\Gamma$  is evaluation at  $\{0\}$ , while the left adjoint Lconst maps  $C \in \mathcal{C}$  to the sheafification of the constant pre-sheaf with value C.

Remark 2.2. Every presentable  $\infty$ -category  $\mathcal{C}$  is uniquely cotensored over  $\mathcal{S}$ , see [Lur09, Remark 5.5.2.6]. More explicitly, for every space S and object C, there is an object  $C^S$  together with a natural equivalence

$$\operatorname{Hom}_{\mathfrak{C}}(S, \operatorname{Hom}_{\mathfrak{C}}(-, C)) \simeq \operatorname{Hom}_{\mathfrak{C}}(-, C^S)$$

**Definition 2.3.** Denote by Sing the functor  $\mathcal{M}fd \to \mathcal{S}$  mapping a manifold to its underlying space. Given a presentable  $\infty$ -category  $\mathcal{C}$ , denote by  $\flat$  the composition  $\mathcal{C} \to \operatorname{Fun}(\mathcal{S}^{op}, \mathcal{C}) \to \operatorname{Fun}(\mathcal{M}fd^{op}, \mathcal{C})$ , the first functor coming from Remark 2.2, the second being pre-composition with Sing<sup>op</sup>.

Explicitly, given an object  $C \in \mathcal{C}$ , the associated pre-sheaf bC maps a manifold M to  $C^{\operatorname{Sing}(M)}$ .

**Lemma 2.4** ([BG21, Corollary 6.46]).  $\flat$  factors through  $Shv(Mfd, \mathcal{C}) \subseteq Fun(Mfd^{op}, \mathcal{C})$ .

Lemma 2.4 is the direct consequence of a weaker version of a generalized version of Seifert-van Kampen theorem, namely [Lur17, Proposition A.3.2], stating that, given a topological space X and a covering sieve  $\mathcal{O}$ , the space  $\mathrm{Sing}(X)$  is the colimit of  $\mathrm{Sing}(U)$  over  $U \in \mathcal{O}$ .

**Theorem 2.5.**  $\flat : \mathcal{C} \to \operatorname{Shv}(\operatorname{Mfd}, \mathcal{C})$  is left adjoint to  $\Gamma$ .

*Proof.* The composition  $\mathcal{C} \xrightarrow{\flat} \operatorname{Shv}(\operatorname{Mfd},\mathcal{C}) \xrightarrow{j_*} \operatorname{Shv}(\operatorname{\mathcal{E}uc},\mathcal{C})$  maps an object C to the sheaf  $\flat C$  restricted to Euclidean spaces. Since  $\mathbb{R}^n$  is contractible,  $(\flat C)(\mathbb{R}^n) = C^{\operatorname{Sing}(\mathbb{R}^n)} \simeq C$  and so  $\flat$  restricted to  $\operatorname{\mathcal{E}uc}$  is equivalent to Const, the functor taking C to the the pre-sheaf with constant value C, which is left adjoint to  $\Gamma$  restricted to  $\operatorname{\mathcal{E}uc}$ .

#### 3. Sheaves of complexes and spectra

The stable Dold-Kan correspondence allows us to move freely between sheaves of  $H\mathbb{Z}$ -module spectras and sheaves valued in  $\mathcal{D}(\mathbb{Z})$ .

Remark 3.1. We identify the category of cochain complexes with Ch(R) by reversing grading. Namely, given a cochain  $V^*$ , we are implicitly identifying it with the chain complex  $V_n = V^{-n}$ .

**Definition 3.2** ([BNV16, Definition 7.14]). Given  $n \in \mathbb{Z}$ , denote by  $\tau^{\geq n}$ , resp.  $\tau^{\leq n}$ , the naive truncation functors, mapping a cochain complex  $V^*$  to

$$\cdots \to 0 \to V^n \to V^{n+1} \to \cdots$$
, resp.  $\cdots \to V^{n-1} \to V^n \to 0 \to \cdots$ 

Given  $F: \mathcal{M}fd^{op} \to \mathrm{Ch}(\mathbb{Z})$ , denote by  $F^{\geq n}$  the composite  $\mathcal{M}fd^{op} \xrightarrow{F} \mathrm{Ch}(\mathbb{Z}) \xrightarrow{\tau^{\geq n}} \mathrm{Ch}(\mathbb{Z})$ , and similarly we define  $F^{\leq n}$ . If F is a sheaf, then so are its truncations.

**Lemma 3.3** ([BNV16, Lemma 7.12]). Let  $F : \mathcal{M}fd^{op} \to \mathrm{Ch}(\mathbb{Z})$  a sheaf of chain complexes of  $C^{\infty}$ -modules, then  $\mathcal{M}fd^{op} \xrightarrow{F} \mathrm{Ch}(\mathbb{Z}) \to \mathcal{D}(\mathbb{Z})$  is a sheaf.

**Definition 3.4.** Denote by  $\Omega^*$  the sheaf  $Mfd^{op} \to Ch(\mathbb{Z})$  mapping a manifold to its de Rham complex.

Lemma 3.3 ensures that the sheaf in Definition 3.4 and the corresponding naive truncations remain sheaves after post-composition with the localization functor  $Ch(\mathbb{Z}) \to \mathcal{D}(\mathbb{Z})$ .

**Definition 3.5.** Given a sheaf  $F: \mathcal{M}fd^{op} \to \mathcal{D}(\mathbb{Z})$ , denote by HF the Eilenberg-Mac Lane sheaf of  $H\mathbb{Z}$ -module spectra obtained by applying point-wise the equivalence of Theorem 1.10.

Recall now the machinery set-up in Section 2.

Remark 3.6. Since  $\mathcal{D}(\mathbb{Z})$  is presentable, we know that they is cotensored over S. Given a space S and a chain complex  $M_*$ , the cotensor  $M_*^A$  is the chain complex of graded linear maps  $C_*(S,\mathbb{Z}) \to M_*$ , from the singular chain complex of S to  $M_*$ , see [Lur17, Definition 1.3.2.1]. In particular, let  $M_* = M$  be concentrated in degree 0, then  $M_*^S$  is the singular cochain complex of S with values in M.

Applying Remark 3.6, we see that  $(\flat A)(M)$  is the singular cochain complex of (the underlying topological space of) M with values in A. In particular for  $A = \mathbb{R}$ , consider the natural map  $\Omega^*(M) \to C^*(M,\mathbb{R})$  taking a form  $\omega \in \Omega^n(M)$  to  $\int \omega : C_n(M,\mathbb{Z}) \to \mathbb{R}$ . We call the induced natural transformation  $dR : \Omega^* \to \flat \mathbb{R}$  the de Rham homomorphism.

**Lemma 3.7.** dR is an equivalence.

*Proof.* The statement is equivalent to dR being an equivalence after restriction to the Euclidean site  $\mathcal{E}$ uc, the conclusion then follows from Poincaré lemma.

### 4. Deligne Cohomology

Finally, we have enough machinery to talk about Deligne cohomology.

**Definition 4.1.** Given  $\ell \in \mathbb{N}$ , define  $\hat{\mathbb{Z}}(\ell) : \mathcal{M}fd^{op} \to \mathcal{D}(\mathbb{Z})$  as the limit of

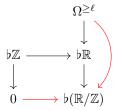

The vertical morphism being the composition  $\Omega^{\geq \ell} \subseteq \Omega^* \xrightarrow{\mathrm{dR}} \flat \mathbb{R}$ . We call the corresponding sheaf of  $H\mathbb{Z}$ -modules spectra  $H\hat{\mathbb{Z}}(\ell)$  the  $\ell$ -th Deligne sheaf.

Remark 4.2 (Model A, see [HS05, §3.2]). Let  $\check{C}(\ell)^n(M) \subseteq C^n(M,\mathbb{Z}) \oplus C^{n-1}(M,\mathbb{R}) \oplus \Omega^n(M)$  consist of triples  $(c,h,\omega)$  for which  $\omega=0$  if  $n<\ell$ , with differential  $\delta(c,h,\omega)=(\delta c,\mathrm{dR}(\omega)-c-\delta h,d\omega)$ . This complex  $\check{C}^*(\ell)(M)$  fits into a diagram

$$\overset{\check{C}^*(\ell)(M)}{\downarrow} \longrightarrow \Omega^{\geq \ell}(M) 
\downarrow \qquad \qquad \downarrow 
C^*(M, \mathbb{Z}) \longrightarrow C^*(M, \mathbb{R})$$

which commutes up to homotopy given by the projections  $\check{C}^n(\ell)(M) \to C^{n-1}(M,\mathbb{R})$ . The diagram above model the homotopy pullback of Definition 4.1, hence  $\check{C}^*(\ell)(M)$  is a model for  $\hat{\mathbb{Z}}(\ell)(M)$ .

Remark 4.3 (Model B). Recall that  $\flat$  preserves cofiber sequences, since it is left adjoint, and that fiber sequences are the same a cofiber sequences in stable  $\infty$ -categories. Consider the diagram

Since the square is an homotopy pullback,  $\hat{\mathbb{Z}}(\ell)(M)$  is equivalent to the homotopy pullback of the diagram in red. Let  $\hat{C}^n(\ell)(M) \subseteq C^{n-1}(M, \mathbb{R}/\mathbb{Z}) \oplus \Omega^n(M)$  consist of pairs  $(\chi, \omega)$  for which  $\omega = 0$  if  $n < \ell$ , with differential  $\delta(\chi, \omega) = (e^{2\pi i d\mathbb{R}(\omega)} - \delta\chi, d\omega)$ . Similar to Remark 4.2, the complex  $\hat{C}^*(\ell)(M)$  fits into the above diagram, so that the outer square is an homotopy pullback.

Take an  $\ell$ -cocycle in the model from Remark 4.3, i.e.  $(\chi, \omega) \in C^{\ell-1}(M, \mathbb{R}/\mathbb{Z}) \oplus \Omega^{\ell}(M)$  such that  $d\omega = 0$  and  $\delta \chi = e^{2\pi i dR(\omega)}$ . Such a cocycle determines a differential character of degree  $\ell - 1$  for M, in the sense of the following definition:

**Definition 4.4** ([HS05, Definition 3.4], see also [BB14, Chapter 5]). Consider a manifold M, a differential character of degree n consists of a character  $\chi: Z_n^{\infty}(M,\mathbb{Z}) \to \mathbb{R}/\mathbb{Z}$  on the group of smooth n-cycles of M together with a n-form  $\omega \in \Omega^{n+1}(M)$ , such that, for every smooth (n+1)-chain c,

$$\chi(\partial c) = e^{2\pi i \int_c \omega}$$

Remark 4.5 (Model C, see [ADH21, Lemma 7.3.4]). Consider the following diagram

Remark 4.6 (Model B'). Consider the following diagram

$$C^{\infty}(-,\mathbb{Z}) \longrightarrow C^{\infty}(-,\mathbb{R})$$

$$\downarrow \qquad \qquad \downarrow$$

$$0 \longrightarrow C^{\infty}(-,S^{1})$$
